Abstract

Rising population and demands for rice as a staple food have created severe stress on freshwater availability for paddy cultivation. The literature suggests that conventional irrigation techniques are inadequate to overcome the water constraints arising from drought and extreme weather conditions. In the past few decades, there is an upsurge of scientific exploration of agricultural techniques in reinventing traditional methods of irrigation. Recently, alternate wet and dry irrigation (AWDI) method has shown great promise regarding profitable rice cultivation with limited water supply. The AWDI method is a trending water management system, which inundates rice fields with intermittent wet conditions followed by a dry period. This not only ensures adequate water supply but increases crop yield and water productivity index (WPI). The AWDI also helps in reducing parasitic mosquito population in the rice fields by minimizing the field flooding period and curtailing a major part of their life cycles. This review proposes a novel approach of emphasizing AWDI method as an important agricultural tool for supplementing rice fields with limited freshwater, increasing crop yield, and monitoring parasitic mosquito populations. The major objective of this study is to report the state-of-the-art scenario of AWDI method, critically analyze the research gaps related to conventional methods of irrigation and appreciate the futuristic long-term benefits of AWDI method. Literature survey was performed using search engines like Scopus, PubMed, Google Scholar, Research Gate, Science Direct, and Google Scholar. Comprehensive appraisal of resources (both offline and online) and critical evaluation of AWDI technicalities revealed that the AWDI reduced water usage by 45%, enhanced crop yield and improved WPI in paddy fields in the Asian sub-continent. The AWDI also curtailed the propagation of lethal mosquito species (Cx. tritaenorhynchus, Cx. vishnui, and Cx pseudovishnui) in rice fields. Therefore, the current study endorses AWDI as a promising substitute of conventional irrigation and a novel approach towards fulfilling water constraints that may be practiced anywhere in the world.

ABSTRACT

Introduction: Japanese Encephalitis (JE) is a life-threatening disease, especially in the Indian subcontinent. Knowledge about the nature and ecology of the dispersal of JE virus (JEV) vectors needs to be increased. This study mechanistically explores the ecology of JEV vectors and the mode and frequency of occurrence of Acute Encephalitis Syndrome (AES) and JEV infections.

Methods: We established a linear relationship between environmental variables and JEV infection by JEV vectors (mosquitoes)—*Culex tritaeniorhynchus, Culex vishnui,* and *Culex pseudovishnui.* The relative abundance of three mosquito species was evaluated, and the JE Sample Positivity Rate (SPR) and JE Case Fatality Rate (CFR) were computed.

Results: *Culex vishnui* had a high abundance in residential areas during the transition from hot-dry (77.34%) to hot-wet period (78.66%) at temperatures between 31°C and 34°C and relative humidity of 80%–85.3%; this period also coincided with occurrence of AES (39 cases in hot-dry and 88 cases in hot-wet period) and JE (8 instances in hot-dry and 31 cases in hot-wet period). JE infection dominated near rainfed rice fields (rainfall: R = 0.67 at p < 0.05; rainy days: R = 0.74, p < 0.01). SPR was up to 32.28%, and CFR was as high as 42.86%; JEV infection was concentrated in adult male humans near rice fields (15.66%).

Conclusions: Climate modulation over the years can influence the distribution of *Culex vishnui* and, hence, AES and JE cases. JEV infections tend to rise in JE hotspot regions, especially near rice fields. Thus, comprehensive epidemiological investigations will help prevent a silent outbreak of JE.

1 | Introduction

Japanese Encephalitis (JE) is one of the most lethal viral diseases, and every year, around 68,000 people get infected with JE virus (JEV), recording up to 10,000 fatal cases in 20 different countries (Campbell et al. 2011; Kulkarni et al. 2018; Tandale et al. 2023). JE is a zoonotic disease caused by a *Flaviviridae* virus, which propagates in a cyclic pattern in mosquitoes, that is, the primary vector (Kulkarni et al. 2018). The lifecycle of JEV vectors also includes water birds and pigs (Dutta 2011; Khan

et al. 2021; Levesque et al. 2024). Epidemiological exploration of JEV infection shows that JE incidences in Southeast Asian countries are yet increasing, and fatality rates have been high for the past two decades (Tandale et al. 2021). The World Health Organisation's Vaccine-Preventable Communicable Diseases, India, reported 1320 JE cases in 2023. Since AES is a generic description of the clinical presentation of a disease characterised by elevated temperature, altered consciousness, etc., it is invariably related to JEV disease (Kakoti et al. 2014; Mehta et al. 2021).
